**Abstract**

In a system, method, GUI, apparatus, and/or computer-readable media for providing a secure, proximity based peer-to-peer payment transaction service a signal may be received from a personal electronic device (PED) by a server. An identity of the PED may be verified based on the received signal and, upon verification the PED may be enabled to discover one or more offers to participate in a transaction provided by one or more sellers. A selection and acceptance of an offer may be received from the PED and funds to a seller providing the selected offer.
